1 Introduction

Refactoring is the process of restructuring code in order to improve the internal behavior of the code, without changing the external behavior.[1]

Code clones are a problem ...

Many tools exist which ...

2 Background

2.1 Software quality

2.1.1 Bad smells

2.1.2 Software quality metrics

2.1.3 How refactoring affects software quality

2.1.4 Duplicated code

Write about what duplicated code is, how it affects software and some statistics on duplicated code (need reference)

2.2 Code clones

We define a code snippet as a piece of software code in a larger software system. A code clone is then defined as a code snippet which is equal to or similar to another code snippet. The two code snippets are both code clones and together, they form a code clone pair.

2.3 The clone relation

The clone relation defines a relationship between code snippets where clones are related to each other. The clone relation is reflexive and symmetric, but not always transitive. The transitive property depends on the threshold for similarity when identifying code clones. For example if we have:

$$a \xrightarrow{\text{clone}} b \xrightarrow{\text{clone}} c$$

where a, b, c are code snippets and $\xrightarrow{\text{clone}}$ gives the clone relation. In this example a may be similar to b , but not necessarily similar to c , depending on the threshold for similarity.

2.3.1 Code clone types

Code clones are generally classified into four types.[2] These types classify code snippets as code clones with an increasing amount of leniency. Therefore Type-1 code clones are very similar, while Type-4 clones are not necessarily similar at all. However, all code clones do still have the same functionality, it is the syntactic and structural differences which distinguish the types. The set of code clones classified by a code clone type is also a subset of the next type, meaning all type-1 clones are also type-2 clones, but not vice versa.

The code clone types are defined as follows:

Type-1 clones are syntactically identical. The only differences allowed are elements without meaning, like comments and white-space.

Type-2 clones are structurally identical. Possible differences include identifiers, literals and types.

Type-3 clones are required to be structurally similar, but not equal. Differences include statements which are added, removed or modified. For this clone type one needs to determine a threshold θ which determines how structurally different snippets can be to be considered Type-3[2].

Type-4 are clones without any requirement for structural similarity. Therefore the only requirement is the functionality being the same.

2.4 Code clone detection

2.5 Code clone management

3 The way forward
